```
How to get LSV clusters running - Step by Step Guide
 1
 2
 3
    by Alexander Wehner
 4
 5
    Prerequisites:
            - OS: any Linux distribution, or alternatively WSL (Windows Subsystem for
 6
    Linux) if you're currently on Windows (how to WSL: https://learn.microsoft.com/en-us/
    windows/wsl/install )
 7
                    (ssh should also be working out of the box on the Windows command line,
    but I don't know if there are any intricacies with that and if it will work just as
    good as on Linux)
8
            - very basic knowledge of how to use the Linux command line (necessary to
9
    connect to (using ssh) and work on the cluster nodes, which run on Ubuntu)
                    (I will walk you through the basics as good as I can)
10
11
            - a copy of the project folder for the cluster that I put here (in this
12
    repository you are currently looking at):
13
                    https://github.com/alexanderwehner/SoPro Neural Networks 25
14
15
16
            - LSV account, working and password changed from master to your own password
17
            - ssh installed (should come preinstalled on pretty much any Linux disto, but
18
    if not, install via the command 'apt install ssh' (e.g. for Ubuntu)
                    or use any other package manager of your choice)
19
20
            - note: wherever I have put the [yourUsername] placeholder, replace it with
21
    just your username, drop the square brackets (and don't put any whitespaces in or
    something like that)
22
23
24
    Disclaimer:
25
26
            I have explicitly written this guide assuming you don't know how to operate a
    Linux terminal, to make sure everyone understands what we are doing, even without
    having any Linux experience.
            I tried to go into great detail on each step, explaining the commands you need
27
    and how to use them, even for the most basic commands.
            If you already are using Linux and have some experience working with the Linux
28
    terminal, much of this guide will feel redundant and overly detailed.
            I made this decision because I wanted to make sure that everyone can not just
29
    reproduce but also understand what they are doing, even if they have no Linux
    experience.
30
            This guide is the compiled documentation of my work setting up the project
```

This guide is the compiled documentation of my work setting up the project files for the cluster and HTCondor infrastructure, as straightforward as possible, as detailed as needed.

The LSV Wiki's guide on HTCondor and the README files in /sopro25 as well as / sopro25/submit-files, which were written by Marius Mosbach, provide some more insight in how to use HTCondor.

Make sure to check that out if you need more information.

33 34

32

```
35
            In case you have any questions or need help setting up HTCondor yourself, do
    not hesitate to contact me, I will help you with anything you need as well as I can.
36
37
38
    Some tips in advance:
39
            - While working with the terminal / command line, make extensive use of the
40
    autocomplete function, by pressing Tab whenever possible (unsure if Windows terminal
    also has this).
                    It will autocomplete fully or partially (if in doubt), when you start
41
    typing the name of a file or directory you want to interact with and then press Tab.
                    It will make your life much easier.
42
43
            - If at any point you need to edit a file once it is already on a cluster node,
44
    you can use the command 'nano [filename]' to edit it from the terminal (must be in the
    same directory).
45
46
47
    Some essential Linux console commands you will need:
48
49
50
                                    prints out the current working directory and path
51
    pwd
    (where you are)
52
53
    cd [directory]
                                    go to the specified directory (you navigate, but
    forward only)
54
                                    navigate to the parent folder ("Go back 1 step". You
55
    cd ..
    can also go back more steps by using 'cd ../.. 'or 'cd ../.. 'etc.)
56
57
    cd ~
                                    navigate to your home directory (' /nethome/
    [yourUsername] '), from anywhere.
58
59
                                    list all contents (subdirectories and files) of the
    directory you are currently in
60
                                    create a new directory X in the directory you are
61
    mkdir [X]
    currently inside of. ("Make new directory [X] here".)
62
                                    delete a file or directory. Add flag ' -r ' to also
63
    recursively delete the contents of a directory. ("Remove [X]".)
64
65
    nano [file]
                                    edit a file inside the terminal using the nano editor,
    when you need to edit files that are already on the remote node. (nano > vim)
66
67
    ssh [destination]
                                    connect to some remote node via SecureShell, the LSV
    cluster, for example: ' ssh [yourUsername]@contact.lsv.uni-saarland.de '
68
    man [command]
                                    displays a manual page for the specified command, where
69
    you can read more on what it does and how to use it
70
71
    scp -r [sourcepath] [destination:path] - securely copy directories /
```

```
files via SecureShell (ssh).
72
             A practical example of me copying a folder (directory) from my device to the
73
     LSV cluster node would look like this:
74
75
                     scp -r ~/Desktop/sopro cluster setup/projects/sopro25
     awehner@contact.lsv.uni-saarland.de:/nethome/awehner/projects
76
               [command] [path on my machine to the file I want to copy] [my LSV user
77
     account, '@', hostname of the target, ':', destination path]
78
79
80
81
     Outline of the file registry structure on the LSV cluster:
82
     (Your account and data in the registries outlined below are available on every node.
83
     There are far more directories on each node, but only the following matter to us):
84
85
86
     |_____/data
87
                 |_____/users
88
89
                             |_____ /[yourUsername]
90
                                               |_____/logs
91
92
     /nethome
93
94
                     |_____ /[yourUsername]
95
                                     |_____/projects
                                                     |_____ /sopro25 (we will copy this
96
     directory here ourselves, details below)
97
98
99
     This is what the file registry structure should look like. In case something does not
     work right away, please make sure all paths outlined here exist (if not, please create
     the relevant missing registries, details on how to do that below).
100
101
     Your home registry (' /~ ') will be /nethome/[yourUsername], so we will put all your
     project files in the /projects directory there (create the directory if it's not there,
     details below). In this guide, I will go into detail about how to get code running and
     submit jobs to the cluster using HTCondor (the system that manages, queues and executes
     jobs on the cluster).
102
103
104
105

    Download the sopro25 project folder from here: https://github.com/alexanderwehner/

     SoPro Neural Networks 25
106
107
108
109
     2. Open the following three files in an editor of your choice:
110
```

the

ls command, if not, create it using the command: 157 158 mkdir projects 159 160 Then, use 1s again to confirm you have created it there. 161 Next navigate to /data/users/[yourUsername] and check if /logs exists, if not, 162 create /logs with: 163 164 mkdir logs 165 You can again check with the ls command if it's now there. 166 167 168 169 170 6. Copy over the data from your machine to the cluster node. 171 172 Open a fresh terminal (that's not logged in to the cluster node via ssh) and copy over the sopro25 project folder from your machine to /nethome/[yourUsername]/projects on the remote node, using the scp -r command: 173 174 For example, from my machine it would be this (first argument: source, second argument: destination, -r flag to recursively copy the folder's content): 175 176 scp -r ~/Desktop/sopro_cluster_setup/projects/sopro25 awehner@contact.lsv.uni-saarland.de:/nethome/awehner/projects 177 You will be prompted to enter your password again, so just enter it and confirm 178 with Enter. 179 180 Once you have finished copying the files, switch back to the other terminal that's connected to the node and navigate to /nethome/[yourUsername]/projects and use the 1s command to check if the directory is there. 181 182 183 7. Build and push the docker image. 184 185 Now you need to connect (from the contact.lsv.uni-saarland.de node) to workstation 71 of the LSV cluster, which we can use to build docker images and push them to the LSV docker registry. 186 Use the command: 187 188 189 ssh [yourUsername]@ws71lx.lsv.uni-saarland.de 190 191 to connect to the workstation, enter your password when prompted and confirm with enter. 192 193 Here, you can also access your data like you would on the contact node. 194 Navigate to /projects/sopro25/docker and build the docker image using the 195 following command: 196

```
197
             IMPORTANT NOTES:
198
             - You have to edit the command to include your username towards the end where I
     put the [yourUsername] placeholder.
             - When executing the command, include the whitespace and dot at the very end,
199
     it is part of the command.
200
201
                     docker build -f Dockerfile --build-arg USER_UID=$UID --build-arg
     USER_NAME=$(id -un) -t docker.lsv.uni-saarland.de/[yourUsername]/
     dockerimage_sopro25:v1 .
202
             Lastly, after you finished building the image, push it to the LSV docker
203
     registry with this command (again, you will need to replace the placeholder with your
     username towards the end):
204
205
                     docker push docker.lsv.uni-saarland.de/[yourUsername]/
     dockerimage sopro25:v1
206
207
             After successfully pushing the image to the registry, log out of the
     workstation node by simply typing the command 'logout' into the terminal.
208
209
             You should now be back to the contact node.
210
     8. Submit a job
211
212
213
             From the contact node, connect to the submit node by using the following
     command:
214
                     ssh [yourUsername]@submit.lsv.uni-saarland.de
215
216
217
             Enter your password when prompted, confirm with Enter.
218
219
             I have prepared a HTCondor submitfile (' run.sub ') that should work out of the
     box with the paths and struture we have created so far.
220
221
             Submit the job by using the following command (remember to put in your username
     instead of the placeholder):
222
223
                     condor_submit /nethome/[yourUsername]/projects/sopro25/submit-files/
     run.sub
224
225
             If it does not immediately throw you any errors, it will first tell you which
     cluster it has submitted your job to (a five digit number).
226
             Remember this number, as it tells you which of the logfiles correspond to that
     exact job submission.
227
228
             You can then monitor your job with the command:
229
230
                     watch condor g [yourUsername]
231
232
             There you can see the status of all your jobs and check if they are still
     running, on hold, rejected or finished.
233
             Wait to see when the job finishes. It usually takes up to a minute to
234
     complete,
```

depending on availability of the compute node we are running on. 235 Once the job finishes, exit this monitor by pressing CTRL + C once, to 236 interrupt the monitor process. 237 238 239 240 9. Check if logfiles were produced 241 242 When the job is finished running, navigate back to / and from there to data/ users/[yourUsername]/logs/sopro25/logfiles and check if there is any files in that directory. If everything worked correctly, there should be three files (one .log file, 243 one .out file and one .err file), each named something like this: 244 245 run.sh.(XXXXX).2025 month day somemorenumbers.log/.out/.err 246 The first number in parentheses (XXXXX) will be the cluster/job number from 247 before, the rest will be today's date and then some more numbers. 248 You can check these out using the cat command, like this for example: 249 250 251 cat run.sh.39139.2025_07_28_1753713314.out 252 253 (This was one of my output files, 39139 is the job number, the rest is the date and probably timestamps.) 254 255 (Also, remember to make use of the autocomplete function of your terminal by pressing Tab a lot.) 256 257 If you start typing 'cat run.sh' and then press Tab, it will autocomplete using whats in the folder until a point at which it is unsure of what file exactly you mean. 258 The first time will be until the file extension, as you now have three files with the same name but different file extensions in your directory. 259 Press Tab and you just have to type the extension, to access either file you want to see. 260 If you do this again later, when you have some older and more recent logfiles in the directory, it will autocomplete up to some point in the job number. You will then have to type in the job number to specify, and you can hit Tab 261 again so that you don't have to type the whole thing out. 262 263 264 265 10. Read all three logfiles 266 267 If all paths are working correctly as intended, each job submission will put

If all paths are working correctly as intended, each job submission will put out three files:

- a log file, containing information about the job on the cluster
- an error file, which in case something goes wrong during the job will contain info about why it failed (file empty means the job finished as intended)
- an output file, which will contain the output of your actual project, the code you are trying to run

271

306

311

File: LSV_Cluster_guide_by_Alexander_Wehner.txt 272 I have put a small example task in the project files (you can check out the code in /sopro25/src/mnist.py), to make the cluster actually run something. 273 274 In the output file, you should see some output at the very bottom (way below the long list of packages and CUDA info). It should be some loss and accuracy metrics of two tiny neural networks I have 275 trained and evaluated in the code. 276 If you can see that, the cluster setup works. 277 278 279 280 Troubleshooting in case of errors: 281 282 283 If something goes wrong at any point, it is most likely a path issue. 284 Make sure all relevant paths used in the files exist in your LSV account 285 registry, or create them if necessary. 286 287 If you encounter any errors you don't know how to fix or need help in general, send me a message and I will do my best to help you get things running. 288 289 290 291 Whats next? 292 293 294 - Managing dependencies 295 296 Installing new dependencies (the way I have set it up here) requires building and pushing a new dockerimage each time you update the dependency list in the dockerfile. 297 Just update the Dockerfile and repeat step 7. In the Dockerfile, lines 32 and below contain the dependencies that are 298 currently in the image we're using. 299 Just add whatever you need here in the same format as the ones already there, and docker will install and build them into the image. 300 In the case that you choose to use a new image name, the submission file 'run.sub' needs to be updated with the correct docker image name (line 5, parameter 'docker image') 301 302 303 - Getting the actual project code into the cluster 304 305

Whatever code we want to run on the cluster needs to be put in the /sopro25/src directory .

Following that, the file 'run.sh' (in /sopro25/scripts) will need to be updated with the new path and file name of the code to specify what code to run.

(line 14, under #run code; currently this specifies my example task 'mnist.py')

- Adapting the submitfile to request code execution on specific hardware specs.

- At the moment, the submitfile is set up in a way that requests a specific cluster compute node and some specific hardware specs.
- Lines 12-15 of the submitfile will need to be updated to specify what exact hardware specs are needed for the job at hand.

314

- 315 316
- 317 This guide should just serve as a springboard into the workflow of HTCondor and the LSV cluster for you, if you want to get into it yourself.

318

Also, if you have the time and nerves to spare, you should check out the other README files in the sopro25 project folder. They come from the LSV HTCondor documentation, written by Marius Mosbach, which goes a bit more into detail regarding HTCondor itself, what commands to use and how to handle it in use.

320

321 The project files I used and modified for my own setup are also based on Mr. Mosbach's HTCondor documentation (currently the official working LSV cluster documentation).

322

323 If you find any errors in this document or something does not work as expected, please let me know as soon as possible.

324

325 Alex
